

The few species which only occurred in some of the lochs are noted below. These are also generally distributed in summer, their scarcity in these lochs being due to the late season at which they were visited.

*Daphnia*.—In all the lochs where *Daphnia* occurred, it was as the variety *galeata*, a large form with the head angled.

*Holopedium gibberum*.—Only in Lochs Calavie and an Tachdaidh.

*Leptodora kindtii*.—Only in Loch Monar.

*Polyphemus pediculus*.—An Gead Loch.

*Cyclops strenuus*.—Present in most of the lochs. The *Cyclops* in Loch Calavie were red-spotted.

*Diaphanosoma brachyurum*.—Found in four lochs—an Tachdaidh, Bunacharan, Mullardoch, and Lungard.

*Floscularia pelagica*.—Loch Monar.

*Conochilus*.—Both species, *C. unicornis* (the common lake species) and *C. volvox*, were present in Loch Monar.

*Sponge*.—A fresh-water sponge, species not determined, came up attached to the sounding-rod, from depths of 6 or 8 feet, in Loch a' Mhuilinn. The pieces were long, finger-shaped.
